Editorial

John Watson performs an operation called a *right circular rotation* on an array of integers,  $[a_0, a_1, \dots, a_{n-1}]$ . After performing one *right circular rotation* operation, the array is transformed from  $[a_0, a_1, \dots, a_{n-1}]$  to  $[a_{n-1}, a_0, \dots, a_{n-2}]$ .

Watson performs this operation  $k$  times. To test Sherlock's ability to identify the current element at a particular position in the rotated array, Watson asks  $q$  queries, where each query consists of a single integer,  $m$ , for which you must print the element at index  $m$  in the rotated array (i.e., the value of  $a_m$ ).

## Input Format

The first line contains 3 space-separated integers,  $n$ ,  $k$ , and  $q$ , respectively.

The second line contains  $n$  space-separated integers, where each integer  $i$  describes array element  $a_i$  (where  $0 \leq i < n$ ).

Each of the  $q$  subsequent lines contains a single integer denoting  $m$ .

## Constraints

- $1 \leq n \leq 10^5$
- $1 \leq a_i \leq 10^5$
- $1 \leq k \leq 10^5$
- $1 \leq q \leq 500$
- $0 \leq m \leq N - 1$

## Output Format

For each query, print the value of the element at index  $m$  of the rotated array on a new line.

## Sample Input

```
3 2 3
1 2 3
0
1
2
```

## Sample Output

```
2
3
1
```

## Explanation

After the first rotation, the array becomes  $[3, 1, 2]$ .

After the second (and final) rotation, the array becomes  $[2, 3, 1]$ .

Let's refer to the array's final state as array  $b$ . For each query, we just have to print the value of  $b_m$  on a new line:

- $m = 0$ , so we print **2** on a new line.
- $m = 1$ , so we print **3** on a new line.

3.  $m = 2$ , so we print **1** on a new line.
